# PERMISSIBLE PATTERNS OF PRIMES 

THOMAS J ENGELSMA

#### Abstract

A family of counting functions pertaining to prime k-tuples is introduced. These functions enumerate the permissible patterns of admissible prime k-tuples. The relationships of the functions are described, and properties of the functions are developed. The functions are then used to identify $y=$ 3159 as the smallest value of $y$ that contradicts the second Hardy-Littlewood conjecture which states $\pi(x+y)-\pi(x) \leq \pi(y)$. The functions are also used to determine the validity of the Hardy-Littlewood k-tuples conjecture.

A permissible pattern is the representation of the positions of the primes in an admissible prime tuple. The pattern '.x.x...x.' is a representation of prime tuples with the form $\{b+1, b+3, b+7\}$, one such tuple is $\{11,13,17\}$. The width of a pattern is the number of locations that are represented, the pattern '.x.x...x.' has a width of nine, or $w=9$. The density of a pattern is the number of locations that represent primes, the pattern '.x.x...x.' consists of three locations that represent primes, or $k=3$. The first and last locations of a permissible pattern are identified as the 'boundary locations', where the first location is the 'leading boundary' and the last location is the 'trailing boundary'.

The number of unique permissible patterns for any width can be enumerated using counting functions. A group of these counting functions are those dependant on the width $w$. These functions are $\rho \rho(w), \rho \rho \mathrm{f}(w)$, and $\rho \rho \mathrm{b}(w)$. Another group of functions are those dependant on both the width $w$ and the density $k$. These functions are $\rho(w, k), \rho \mathrm{f}(w, k)$, and $\rho \mathrm{b}(w, k)$.

The counting function $\rho \rho(w)$ is defined as the number of permissible patterns when the width of the pattern is $w$. This function enumerates the number of unique admissible prime tuple variations that can exist in $w$ consecutive integers. As an example, the 35 permissible patterns representing intervals of nine consecutive integers are shown below. Note that the empty pattern '.........' is also a countable pattern. See Table 1 for more values of $\rho \rho()$.

$$
\begin{aligned}
& \text { x....... } x . x . \ldots \text { x.... } x . . . x . x . x_{x} \\
& \text {.x...... .x.x..... .x...x... .x.x...x. } \\
& \text {..x..... ..x.x.... ..x...x.. ..x.x...x } x . . . . x . x \\
& \text {...x.... ...x.x... ...x...x. } \\
& \text {....x.... ....x.x. ....x...x x...x.x.. } \\
& \text {....x... ....x.x. } x \text {...x.x. x.x...x.x } \\
& \text {.....x.. ......x.x x.....x.. ..x...x.x } \\
& \text {......x. .x.....x. } \\
& \text {........x x.......x ..x..... } x
\end{aligned}
$$

The 35 permissible patterns enumerated by $\rho \rho(9)$

The counting function $\rho \rho \mathrm{f}(w)$ is defined as the number of permissible patterns when the width of the pattern is $w$ and the leading boundary represents a prime. This function enumerates the number of unique admissible prime tuple variations that can exist in $w$ consecutive integers when the first integer is a prime. As an example, the 10 permissible patterns representing intervals of nine consecutive integers that start with a prime are shown below. See Table 2 for more values of $\rho \rho f()$.

$$
\begin{aligned}
& \text { x........ x.x...... x.x...x.. } x . x . . . x . x \\
& \text { x...x.... } x . x . \ldots x \\
& \text { x.....x.. x...x.x.. } \\
& \text { x.......x x.....x.x }
\end{aligned}
$$

The 10 permissible patterns enumerated by $\rho \rho f(9)$
The counting function $\rho \rho \mathrm{b}(w)$ is defined as the number of permissible patterns when the width of the pattern is $w$ and both boundary locations represent primes. This function enumerates the number of unique admissible prime tuple variations that can exist in $w$ consecutive integers when the first and last integer are prime. As an example, the 4 permissible patterns representing intervals of nine consecutive integers that start and end with a prime are shown below. See Table 3 for more values of $\rho \rho \mathrm{b}()$.

$$
\begin{array}{ll}
\text { x.......x } & \text { x.x.....x } \\
& \text { x....x.x }
\end{array}
$$

The 4 permissible patterns enumerated by $\rho \rho \mathrm{b}(9)$
The counting function $\rho(w, k)$ is defined as the number of permissible patterns when the width of the pattern is $w$ and the density of the pattern is $k$. This function enumerates the number of unique admissible prime tuple variations of $k$ primes that can exist in $w$ consecutive integers. As an example, the 8 permissible patterns representing three primes in an interval of nine consecutive integers are shown below. See Table 1 for more values of $\rho()$.

$$
\begin{array}{ccc}
\text { x.x...x.. } & \text { x...x.x.. } & \text { x.x.....x } \\
. x . x . \ldots x . & . x . \ldots x . x . & x . \ldots . x . x \\
\ldots x . x . . x & \ldots x . . x . x &
\end{array}
$$

The 8 permissible patterns enumerated by $\rho(9,3)$
The counting function $\rho \mathrm{f}(w, k)$ is defined as the number of permissible patterns when the width of the pattern is $w$, the density of the pattern is $k$, and the leading boundary represents a prime. This function enumerates the number of unique admissible prime tuple variations of $k$ primes that can exist in $w$ consecutive integers when the first integer is a prime. As an example, the 4 permissible patterns representing three primes in an interval of nine consecutive integers that start with a prime are shown below. See Table 2 for more values of $\rho \mathrm{f}()$.

$$
\begin{array}{ll}
\text { x.x...x.. } & \text { x.x.....x } \\
\text { x...x.x. } & \text { x.....x.x }
\end{array}
$$

The 4 permissible patterns enumerated by $\rho f(9,3)$

The counting function $\rho \mathrm{b}(w, k)$ is defined as the number of permissible patterns when the width of the pattern is $w$, the density of the pattern is $k$, and both boundary locations represent primes. This function enumerates the number of unique admissible prime tuple variations of $k$ primes that can exist in $w$ consecutive integers when the first and last integers are prime. As an example, the 2 permissible patterns representing three primes in an interval of nine consecutive integers that start and end with a prime are shown below. See Table 3 for more values of $\rho \mathrm{b}()$.
x.x.....x x.....x.x

The 2 permissible patterns enumerated by $\rho \mathrm{b}(9,3)$
A permissible pattern consists of one or more locations, meaning the width is one or greater. No permissible pattern has a width of zero, therefore the counting functions $\rho \rho(w)$ and $\rho(w, k)$ are undefined for widths of zero.

$$
\rho \rho(w) \text { and } \rho(w, k) \quad \text { are undefined for } \quad w \leq 0
$$

The counting functions $\rho \rho \mathrm{f}()$ and $\rho \mathrm{f}()$ enumerate permissible patterns with a prime representation in the leading boundary location. A countable pattern must consist of one or more locations to have a leading boundary, meaning the width is one or greater. No permissible pattern with a leading boundary location has a width less than one, therefore the counting functions $\rho \rho \mathrm{f}(w)$ and $\rho \mathrm{f}(w, k)$ are undefined for widths less than one.

$$
\rho \rho \mathrm{f}(w) \text { and } \rho \mathrm{f}(w, k) \quad \text { are undefined for } \quad w<1
$$

Also, a countable pattern must consist of a prime representation in the leading boundary, meaning the density is one or greater. No permissible pattern with a prime representation in the leading boundary has a density less than one, therefore the counting function $\rho \mathrm{f}(w, k)$ is undefined for densities less than one.

$$
\rho \mathrm{f}(w, k) \quad \text { is undefined for } \quad k<1
$$

The counting functions $\rho \rho \mathrm{b}()$ and $\rho \mathrm{b}()$ enumerate permissible patterns with a prime representation in both the leading and trailing boundary locations. A countable pattern must consist of two or more locations to have both a leading and trailing boundary, meaning the width is two or greater. No permissible pattern with a leading and trailing boundary location has a width less than two, therefore the counting functions $\rho \rho \mathrm{b}(w)$ and $\rho \mathrm{b}(w, k)$ are undefined for widths less than two.

$$
\rho \rho \mathrm{b}(w) \text { and } \rho \mathrm{b}(w, k) \quad \text { are undefined for } \quad w<2
$$

Also, a countable pattern must consist of a prime representation in both the leading and trailing boundary, meaning the density is two or greater. No permissible pattern with a prime representation in both the leading and trailing boundary has a density less than two, therefore the counting function $\rho \mathrm{b}(w, k)$ is undefined for densities less than two.

$$
\rho \mathrm{b}(w, k) \quad \text { is undefined for } \quad k<2
$$

The counting functions $\rho(), \rho \mathrm{f}()$, and $\rho \mathrm{b}()$ enumerate permissible patterns with a width of $w$ and a density of $k$. A countable pattern must consist of $w$ locations, meaning the density can be no greater than $w$. No permissible pattern can have a density greater than the width, therefore no permissible patterns can exist when the density is greater than the width.

$$
\begin{array}{rlll}
\rho(w, k)=0 & \text { when } & k>w \\
\rho \mathrm{f}(w, k)=0 & \text { when } & k>w \\
\rho \mathrm{~b}(w, k)=0 & \text { when } & k>w
\end{array}
$$

A permissible pattern that consists of only non-prime representations has a density of zero and is known as an 'empty pattern'. Only one empty pattern exists for each width, therefore $\rho(w, 0)=1$ for widths of one or greater.

$$
\rho(w, 0)=1 \quad \text { for all } \quad w \geq 1
$$

These counting functions can be viewed as sets of patterns in the universe of all possible patterns. As shown below the patterns enumerated by each counting function are a subset of all $2^{w}$ possible patterns for the width $w$. Also shown is the hierarchy of the counting functions. The counting function $\rho \rho(w)$ has the broadest range where each of the five other counting functions are proper subsets of $\rho \rho(w)$. The counting function $\rho \mathrm{b}(w, k)$ has the narrowest range because it is a proper subset in each of the five other counting functions.

The six counting functions viewed as sets
The counting function $\rho \rho(w)$ enumerates all permissible patterns with a width of $w$ while the counting function $\rho(w, k)$ enumerates all permissible patterns with a width of $w$ and a density of $k$. Every pattern enumerated by $\rho(w, k)$ is also enumerated by $\rho \rho(w)$.

$$
\begin{align*}
& \rho \rho(w)=\rho(w, w)+\rho(w, w-1)+\ldots+\rho(w, 1)+\rho(w, 0) \\
& \rho \rho(w)=\sum_{j=0}^{w} \rho(w, j) \quad \text { for all } \quad w>0 \tag{1}
\end{align*}
$$

The counting function $\rho \rho f(w)$ enumerates all permissible patterns with a width of $w$ and a prime representation in the leading boundary location while the counting function $\rho \mathrm{f}(w, k)$ enumerates all permissible patterns with a width of $w$, a density of $k$, and a prime representation in the leading boundary location. Every pattern enumerated by $\rho \mathrm{f}(w, k)$ is also enumerated by $\rho \rho \mathrm{f}(w)$.

$$
\begin{align*}
& \rho \rho \mathrm{f}(w)=\rho \mathrm{f}(w, w)+\rho \mathrm{f}(w, w-1)+\ldots+\rho \mathrm{f}(w, 2)+\rho \mathrm{f}(w, 1) \\
& \rho \rho \mathrm{f}(w)=\sum_{j=1}^{w} \rho \mathrm{f}(w, j) \quad \text { for all } \quad w \geq 1 \tag{2}
\end{align*}
$$

The counting function $\rho \rho \mathrm{b}(w)$ enumerates all permissible patterns with a width of $w$ and prime representations in both boundary locations while the counting function $\rho \mathrm{b}(w, k)$ enumerates all permissible patterns with a width of $w$, a density of $k$, and prime representations in both boundary locations. Every pattern enumerated by $\rho \mathrm{b}(w, k)$ is also enumerated by $\rho \rho \mathrm{b}(w)$.

$$
\begin{align*}
& \rho \rho \mathrm{b}(w)=\rho \mathrm{b}(w, w)+\rho \mathrm{b}(w, w-1)+\ldots+\rho \mathrm{b}(w, 3)+\rho \mathrm{b}(w, 2) \\
& \rho \rho \mathrm{b}(w)=\sum_{j=2}^{w} \rho \mathrm{~b}(w, j) \quad \text { for all } \quad w \geq 2 \tag{3}
\end{align*}
$$

The summations created so far have been based on varying the number of prime representations in the patterns. Summations can also be created by varying the width of the patterns. An operation for manipulating a permissible pattern is trimming. Trimming shortens a permissible pattern by truncating either boundary location. The result of this operation is a pattern that represents an admissible prime tuple, therefore the resulting pattern is a permissible pattern. A consequence of the trimming operation is any contiguous sequence of locations within a permissible pattern is itself a permissible pattern.

The counting function $\rho \rho(w)$ enumerates all permissible patterns with a width of $w$. These patterns can be divided into two groups based on the leading boundary. The first group consists of patterns with a prime representation in the leading boundary and the second group consists of patterns with a non-prime representation in the leading boundary. The first group is equivalent to the patterns enumerated by $\rho \rho f(w)$. Trimming the non-prime representation in the leading boundary location from every pattern in the second group of patterns produces the patterns enumerated by $\rho \rho(w-1)$.

$$
\rho \rho(w)=\rho \rho f(w)+\rho \rho(w-1) \quad \text { for all } \quad w \geq 1
$$

This division into two groups can continue for the $\rho \rho()$ term and every successive $\rho \rho()$ term until the width is 1 . The two possible patterns with a width of one are ' $x$ ' and '. '. Both patterns represent admissible prime tuples, therefore $\rho \rho(1)=2$ and $\rho \rho f(1)=1$.

$$
\begin{aligned}
& \rho \rho(w)=\rho \rho \mathrm{f}(w)+\rho \rho \mathrm{f}(w-1)+\ldots+\rho \rho \mathrm{f}(2)+\rho \rho(1) \\
& \rho \rho(w)=\rho \rho \mathrm{f}(w)+\rho \rho \mathrm{f}(w-1)+\ldots+\rho \rho \mathrm{f}(2)+\rho \rho \mathrm{f}(1)+1
\end{aligned}
$$

The counting function $\rho \rho()$ can be expressed as a summation of counting function $\rho \rho \mathrm{f}()$ values. It should be noted that the value of $\rho \rho \mathrm{f}(w) \geq 1$ for all $w \geq 1$, therefore $\rho \rho(w+1)>\rho \rho(w)$, meaning the counting function $\rho \rho()$ is strictly increasing.

$$
\begin{equation*}
\rho \rho(w)=1+\sum_{i=1}^{w} \rho \rho \mathrm{f}(i) \quad \text { for all } \quad w \geq 1 \tag{4}
\end{equation*}
$$

The counting function $\rho \rho f(w)$ enumerates all permissible patterns with a width of $w$ and a prime representation in the leading boundary. These patterns can be divided into two groups based on the trailing boundary. The first group consists of patterns with a prime representation in the trailing boundary and the second group consists of patterns with a non-prime representation in the trailing boundary. The first group is equivalent to the patterns enumerated by $\rho \rho \mathrm{b}(w)$. Trimming the non-prime representation in the trailing boundary location from every pattern in the second group of patterns produces the patterns enumerated by $\rho \rho \mathrm{f}(w-1)$.

$$
\rho \rho \mathrm{f}(w)=\rho \rho \mathrm{b}(w)+\rho \rho \mathrm{f}(w-1) \quad \text { for all } \quad w \geq 2
$$

This division into two groups can continue for the $\rho \rho f()$ term and every successive $\rho \rho f()$ term until the width is 2 . The four possible patterns with a width of two are '..', ' $x$.', '. $x$ ' and ' $x x$ '. The pattern ' $x x$ ' does not represent an admissible prime tuple, therefore $\rho \rho \mathrm{f}(2)=1$ and $\rho \rho \mathrm{b}(2)=0$.

$$
\begin{aligned}
& \rho \rho \mathrm{f}(w)=\rho \rho \mathrm{b}(w)+\rho \rho \mathrm{b}(w-1)+\ldots+\rho \rho \mathrm{b}(3)+\rho \rho \mathrm{f}(2) \\
& \rho \rho \mathrm{f}(w)=\rho \rho \mathrm{b}(w)+\rho \rho \mathrm{b}(w-1)+\ldots+\rho \rho \mathrm{b}(3)+\rho \rho \mathrm{b}(2)+1
\end{aligned}
$$

The counting function $\rho \rho f()$ can be expressed as a summation of counting function $\rho \rho \mathrm{b}()$ values. It should be noted that the value of $\rho \rho \mathrm{b}(w) \geq 0$ for all $w \geq 2$, therefore $\rho \rho \mathrm{f}(w+1) \geq \rho \rho \mathrm{f}(w)$, meaning the counting function $\rho \rho \mathrm{f}()$ is weakly increasing.

$$
\begin{equation*}
\rho \rho \mathrm{f}(w)=1+\sum_{i=2}^{w} \rho \rho \mathrm{~b}(i) \quad \text { for all } \quad w \geq 2 \tag{5}
\end{equation*}
$$

Similar summations can be created for the counting functions that are dependent on both $w$ and $k$. The counting function $\rho(w, k)$ enumerates all permissible patterns with a width of $w$ and a density of $k$. These patterns can be divided into two groups based on the leading boundary. The first group consists of patterns with a prime representation in the leading boundary and the second group consists of patterns with a non-prime representation in the leading boundary. The first group is equivalent to the patterns enumerated by $\rho \mathrm{f}(w, k)$. Trimming the non-prime representation in the leading boundary location from every pattern in the second group produces the patterns enumerated by $\rho(w-1, k)$.

$$
\rho(w, k)=\rho \mathrm{f}(w, k)+\rho(w-1, k) \quad \text { for all } \quad 1 \leq k \leq w
$$

This division into two groups can continue for the $\rho()$ term and every successive $\rho()$ term until the width is $k$. When $w$ equals $k$ all locations of the pattern must
be prime representations, therefore the leading boundary is a prime representation and the enumeration of $\rho(k, k)$ equals the enumeration of $\rho \mathrm{f}(k, k)$.

$$
\begin{aligned}
& \rho(w, k)=\rho \mathrm{f}(w, k)+\rho \mathrm{f}(w-1, k)+\ldots+\rho \mathrm{f}(k+1, k)+\rho(k, k) \\
& \rho(w, k)=\rho \mathrm{f}(w, k)+\rho \mathrm{f}(w-1, k)+\ldots+\rho \mathrm{f}(k+1, k)+\rho \mathrm{f}(k, k)
\end{aligned}
$$

The counting function $\rho()$ can be expressed as a summation of counting function $\rho f()$ values. The counting function $\rho()$ is a strictly increasing function.

$$
\begin{equation*}
\rho(w, k)=\sum_{i=k}^{w} \rho \mathrm{f}(i, k) \quad \text { for all } \quad 1 \leq k \leq w \tag{6}
\end{equation*}
$$

The counting function $\rho \mathrm{f}(w, k)$ enumerates all permissible patterns with a width of $w$, a density of $k$, and the leading boundary location is a prime representation. These patterns can be divided into two groups based on the trailing boundary. The first group consists of patterns with a prime representation in the trailing boundary and the second group consists of patterns with a non-prime representation in the trailing boundary. The first group is equivalent to the patterns enumerated by $\rho \mathrm{b}(w, k)$. Trimming the non-prime representation from every pattern in the second group produces the patterns enumerated by $\rho \mathrm{f}(w-1, k)$.

$$
\rho \mathrm{f}(w, k)=\rho \mathrm{b}(w, k)+\rho \mathrm{f}(w-1, k) \quad \text { for all } \quad 2 \leq k \leq w
$$

This division into two groups can continue for the $\rho \mathrm{f}()$ term and every successive $\rho \mathrm{f}()$ term until the width is $k$. When $w$ equals $k$ all locations of the pattern must be prime representations, therefore the trailing boundary is a prime representation and the enumeration of $\rho \mathrm{f}(k, k)$ equals the enumeration of $\rho \mathrm{b}(k, k)$.

$$
\begin{aligned}
& \rho \mathrm{f}(w, k)=\rho \mathrm{b}(w, k)+\rho \mathrm{b}(w-1, k)+\ldots+\rho \mathrm{b}(k+1, k)+\rho \mathrm{f}(k, k) \\
& \rho \mathrm{f}(w, k)=\rho \mathrm{b}(w, k)+\rho \mathrm{b}(w-1, k)+\ldots+\rho \mathrm{b}(k+1, k)+\rho \mathrm{b}(k, k)
\end{aligned}
$$

The counting function $\rho f()$ can be expressed as a summation of counting function $\rho \mathrm{b}()$ values. The counting function $\rho \mathrm{f}()$ is a weakly increasing function.

$$
\begin{equation*}
\rho \mathrm{f}(w, k)=\sum_{i=k}^{w} \rho \mathrm{~b}(i, k) \quad \text { for all } \quad 2 \leq k \leq w \tag{7}
\end{equation*}
$$

Additional summations can be created by substituting. The counting function $\rho \rho()$ can be expressed as a summation of counting function $\rho \rho \mathrm{b}()$ values by substituting equation (5) into equation (4).

$$
\begin{align*}
& \rho \rho(w)=1+\rho \rho \mathrm{f}(1)+\sum_{i=2}^{w}\left(1+\sum_{j=2}^{i} \rho \rho \mathrm{~b}(j)\right) \\
& \rho \rho(w)=1+w+\sum_{i=2}^{w}(w+1-i) \rho \rho \mathrm{b}(i) \quad \text { for all } \quad w \geq 2 \tag{8}
\end{align*}
$$

The counting function $\rho()$ can be expressed as a summation of counting function $\rho \mathrm{b}()$ values by substituting equation (7) into equation (6).

$$
\begin{align*}
\rho(w, k) & =\sum_{i=k}^{w}\left(\sum_{i i=k}^{i} \rho \mathrm{~b}(i i, k)\right) \\
\rho(w, k) & =\sum_{i=k}^{w} \sum_{i i=k}^{i} \rho \mathrm{~b}(i i, k) \\
\rho(w, k) & =\sum_{i=k}^{w}(w+1-i) \rho \mathrm{b}(i, k) \quad \text { for all } \quad 2 \leq k \leq w \tag{9}
\end{align*}
$$

The counting function $\rho \rho()$ can be expressed as a summation of counting function $\rho f()$ values by substituting equation (2) into equation (4).

$$
\begin{align*}
& \rho \rho(w)=1+\sum_{i=1}^{w}\left(\sum_{j=1}^{i} \rho \mathrm{f}(i, j)\right) \\
& \rho \rho(w)=1+\sum_{i=1}^{w} \sum_{j=1}^{i} \rho \mathrm{f}(i, j) \quad \text { for all } \quad w \geq 1 \tag{10}
\end{align*}
$$

The counting function $\rho \rho f()$ can be expressed as a summation of counting function $\rho \mathrm{b}()$ values by substituting equation (3) into equation (5).

$$
\begin{align*}
& \rho \rho \mathrm{f}(w)=1+\sum_{i=2}^{w}\left(\sum_{j=2}^{i} \rho \mathrm{~b}(i, j)\right) \\
& \rho \rho \mathrm{f}(w)=1+\sum_{i=2}^{w} \sum_{j=2}^{i} \rho \mathrm{~b}(i, j) \quad \text { for all } \quad w \geq 2 \tag{11}
\end{align*}
$$

The counting function $\rho \rho()$ can be expressed as a summation of counting function $\rho \mathrm{b}()$ values by substituting equation (3) into equation (8).

$$
\begin{align*}
& \rho \rho(w)=1+w+\sum_{i=2}^{w}(w+1-i)\left(\sum_{j=2}^{i} \rho \mathrm{~b}(i, j)\right) \\
& \rho \rho(w)=1+w+\sum_{i=2}^{w} \sum_{j=2}^{i}(w+1-i) \rho \mathrm{b}(i, j) \quad \text { for all } \quad w \geq 2 \tag{12}
\end{align*}
$$

As shown in equations (3), (7), (9), (11), and (12), summations of counting function $\rho \mathrm{b}()$ values can be used to express each of the other five counting functions. The counting function $\rho \mathrm{b}()$ is the core function and requires further investigation. An admissible prime tuple that begins and ends with a prime can only exist in an odd number of consecutive integers, otherwise either the beginning or ending number would be divisible by two and could not be a prime. Every pattern that
is countable by the $\rho \mathrm{b}()$ function must have prime representations in both boundary locations, therefore no permissible pattern with prime representations in both boundary locations can exist in a width that is even.

$$
\rho \mathrm{b}(2 x, k)=0 \quad \text { for all } \quad x \geq 1 \text { and } k \geq 2
$$

The patterns that are countable by the $\rho \mathrm{b}()$ function have widths that are odd. Every pattern that is countable by the $\rho \mathrm{b}()$ function must have a density of two or more. When the density is two, the prime representations in both boundary locations are the only prime representations in the pattern. Only one countable pattern with a density of two can exist for each odd width.

$$
\rho \mathrm{b}(2 x+1,2)=1 \quad \text { for all } \quad x \geq 1
$$

The case of $k=2$ is generalized as

$$
\text { for } \quad w \geq 2, \quad \rho \mathrm{~b}(w, 2)= \begin{cases}0 & \text { when } w \text { is even } \\ 1 & \text { when } w \text { is odd }\end{cases}
$$

Trimming the trailing boundary location from a pattern enumerated by $\rho \mathrm{b}(w, k)$ results in a pattern enumerated by $\rho \mathrm{f}(w-1, k-1)$. If the trailing boundary location of the resulting pattern is a prime representation then this resulting pattern is also enumerated by $\rho \mathrm{b}(w-1, k-1)$. If the trailing boundary location of the resulting pattern is a non-prime representation continue trimming the trailing boundary location from the pattern until the trailing boundary location is a prime representation. The final resulting pattern is a pattern enumerated by both $\rho \mathrm{f}(w-a, k-1)$ and $\rho \mathrm{b}(w-a, k-1)$, where $a$ is the number of times the trailing boundary location was trimmed. The number of patterns enumerated by $\rho \mathrm{b}(w, k)$ must be less than or equal to the sum of the number of patterns enumerated by $\rho \mathrm{b}(i, k-1)$ for every $i<w$, provided the initial $w$ is greater than 2 .

$$
\rho \mathrm{b}(w, k) \leq \sum_{i=2}^{w-1} \rho \mathrm{~b}(i, k-1) \quad \text { for all } \quad w>2
$$

This summation can be revised to sum over only odd widths because $\rho \mathrm{b}()$ is equal to zero for all even widths.

$$
\rho \mathrm{b}(2 x+1, k) \leq \sum_{i=1}^{x-1} \rho \mathrm{~b}(2 i+1, k-1) \quad \text { for all } \quad x \geq 1
$$

A generalization is created when this same summation is applied to all of the $\rho \mathrm{b}(2 i+1, k-1)$ terms in the original summation.

$$
\begin{equation*}
\rho \mathrm{b}(2 x+1, k) \leq \sum_{i=1}^{x-k+n}\binom{x-1-i}{k-n-1} \rho \mathrm{~b}(2 i+1, n) \quad \text { when } \quad 2 \leq n<k \tag{13}
\end{equation*}
$$

An upper bound is established by setting $n=2$ in equation (13), thereby allowing the previously established equality of $\rho \mathrm{b}(2 x+1,2)=1$ to be used.

$$
\begin{aligned}
& \rho \mathrm{b}(2 x+1, k) \leq \sum_{i=1}^{x-k+2}\binom{x-1-i}{k-3} \\
& \rho \mathrm{~b}(2 x+1, k) \leq\binom{ x-1}{k-2}
\end{aligned}
$$

This upper bound of $\binom{x-1}{k-2}$ for $\rho \mathrm{b}(2 x+1, k)$ is simply the number of ways to select a subset of $k-2$ elements from a set of $x-1$ elements. The patterns enumerated by $\rho \mathrm{b}(2 x+1, k)$ are of an odd width with a prime representation in both the leading and trailing boundaries. When the width of a pattern is $2 x+1$ there are $x$ locations that must be non-prime representations of the even numbers in the corresponding admissible prime tuple. The remaining $x+1$ locations are available locations for prime representations. Two of these locations are the leading and trailing boundaries which already are prime representations, leaving $x-1$ possible locations for prime representations. The patterns enumerated by $\rho \mathrm{b}(2 x+1, k)$ must also contain $k$ prime representations. Again, two of these representations are in the leading and trailing boundaries, leaving $k-2$ prime representations to be distributed throughout the $x-1$ available locations in the pattern. The upper bound of $\rho \mathrm{b}()$ can be greatly improved by using larger values of $n$ in equation (13). More information about the character of the counting function $\rho \mathrm{b}()$ is required to use a larger value of $n$.

When all factors of an integer in an admissible prime tuple that is enumerated by $\rho \mathrm{b}(w, k)$ are greater than $k$ the location in the corresponding permissible pattern is a 'possible' location for a prime representation. An example of a possible location is in the admissible prime tuple $\{31,37,41,43\}$ that is enumerated by $\rho \mathrm{b}(13,4)$. This integer sequence contains the integer 35 that has the factors 5 and 7 . Both factors are greater than the density of the enumerating function. The location in the permissible pattern representation that corresponds to 35 in the integer sequence is a possible location for a prime representation. The locations of the prime representations in the original permissible pattern are also possible locations for prime representations.

If the number of possible locations exceeds the number of prime representations in a permissible pattern additional permissible patterns can be created. Every combination of $k$ or fewer possible locations creates a valid permissible pattern. Permissible patterns created from $k$ possible locations which include both boundary locations are unique permissible patterns enumerated by $\rho \mathrm{b}(w, k)$. The quantity
of unique permissible patterns that can be created is $\binom{s-2}{k-2}$ where $s$ represents the number of possible locations. If the quantity of possible locations equals the quantity of prime representations the binomial equals one, being the original permissible pattern.

The product of the primes less than or equal to $k$ is commonly known as a primorial, hereby denoted as $\mathbb{P}_{k}$. Applying the 'Sieve of Eratosthenes' on the integers 1 through $\mathbb{P}_{k}$ with all the primes less than or equal to $k$ exposes the integers having all factors greater than $k$. The corresponding locations of these integers are possible locations for prime representations that can be used to create permissible patterns with a density of $k$.

$$
\begin{aligned}
& \mathbb{P}_{6}=2 \cdot 3 \cdot 5=30 \text { locations } \\
& \mathrm{s} 2 \mathrm{~s} 2 \mathrm{~s} 2 \mathrm{~s} 2 \mathrm{~s} 2 \mathrm{~s} 2 \mathrm{~s} 2 \mathrm{~s} 2 \mathrm{~s} 2 \mathrm{~s} 2 \mathrm{~s} 2 \mathrm{~s} 2 \mathrm{~s} 2 \mathrm{~s} 2 \mathrm{~s} 2 \\
& \text { remove every } p_{2}=3 \text { rd integer } \mathrm{s} .3 . \mathrm{s}-\mathrm{s} .3 \mathrm{~s}-\mathrm{s} .3 \mathrm{~s}-\mathrm{s} .3 \mathrm{~s}-\mathrm{s} \cdot 3 . \mathrm{s}- \\

& 8 \text { possible locations s . . . . . s . . . s . s . . . s . s . . . s . . . . . s . }
\end{aligned}
$$

The number of integers exposed in the first $\mathbb{P}_{k}$ integers is calculated as the product of $\left(p_{i}-1\right)$ for all primes $p_{i}$ that are less than or equal to $k$. This product is denoted as $\mathbb{Q}_{k}$. Initial values and equations for the products $\mathbb{P}_{k}$ and $\mathbb{Q}_{k}$ are shown below.

| $k$ | $\pi(k)$ | $p_{\pi(k)}$ | $\mathbb{P}_{k}$ | $p_{\pi(k)}-1$ | $\mathbb{Q}_{k}$ |
| ---: | ---: | ---: | ---: | ---: | ---: |

Values and Equations
of $\mathbb{P}_{k}$ and $\mathbb{Q}_{k}$

$$
\begin{gathered}
\mathbb{P}_{k}=\prod_{i=1}^{\pi(k)} p_{i} \\
\mathbb{Q}_{k}=\prod_{i=1}^{\pi(k)}\left(p_{i}-1\right)
\end{gathered}
$$

$\pi()$ is the prime counting function and $p_{i}$ is the $i$ th prime number

Using Euclid's argument about the infinitude of the primes, the integer after the primorial $\mathbb{P}_{k}$ is not divisible by any prime less than or equal to $k$, and is a possible location for a prime representation in permissible patterns enumerated by $\rho \mathrm{b}\left(\mathbb{P}_{k}+1, k\right)$. Since the number of possible locations in a permissible pattern of $\mathbb{P}_{k}$ locations is $\mathbb{Q}_{k}$, the additional possible location at $\mathbb{P}_{k}+1$ causes the number of possible locations in permissible patterns with a width of $\mathbb{P}_{k}+1$ to be $\mathbb{Q}_{k}+1$. A lower bound for the number of permissible patterns enumerated by $\rho \mathrm{b}\left(\mathbb{P}_{k}+1, k\right)$ is immediately revealed.

$$
\binom{\mathbb{Q}_{k}-1}{k-2} \leq \rho \mathrm{b}\left(\mathbb{P}_{k}+1, k\right)
$$

Consider a prime representation in a permissible pattern enumerated by $\rho \mathrm{b}(w, k)$, the integer in the corresponding admissible prime tuple has a unique set of residues for each prime less than or equal to $k$. When $\mathbb{P}_{k}$ is added to the initial integer the resulting sum has the same set of residues for each prime less than or equal to $k$. Let $a_{1}, a_{2}, \ldots a_{r+1}$ be the possible locations of prime representations for a permissible pattern enumerated by $\rho \mathrm{b}\left(\mathbb{P}_{k}+1, k\right)$ where $r+1$ is the number of possible locations, then $a_{1}, a_{2}, \ldots a_{r+1}$ and $a_{1}+\mathbb{P}_{k}, a_{2}+\mathbb{P}_{k}, \ldots a_{r+1}+\mathbb{P}_{k}$ are possible locations of prime representations for permissible patterns with a density of $k$. As shown, when $a_{i}$ is a possible location, the location at $a_{i}+\mathbb{P}_{k}$ is also a possible location. Every permissible pattern enumerated by $\rho \mathrm{b}\left(\mathbb{P}_{k}+1, k\right)$ is contained in the sequence of possible locations from 1 to $2 \mathbb{P}_{k}$. There are $\mathbb{Q}_{k}$ unique sequences of possible locations that are $\mathbb{P}_{k}+1$ wide with each sequence starting at one of the possible locations from 1 through $\mathbb{P}_{k}$ and ending with one of the possible locations from $\mathbb{P}_{k}+1$ through $2 \mathbb{P}_{k}$. This leads to an upper bound for $\rho \mathrm{b}\left(\mathbb{P}_{k}+1, k\right)$.

$$
\rho \mathrm{b}\left(\mathbb{P}_{k}+1, k\right) \leq \mathbb{Q}_{k}\binom{\mathbb{Q}_{k}-1}{k-2}
$$

Using the same argument as above the sequence of possible locations is shown to repeat for every sequence of $\mathbb{P}_{k}$ locations. The lower and upper bounds are rewritten to reflect this multiple of $\mathbb{P}_{k}$ by including the multiple of $\mathbb{Q}_{k}$ in the binomials.

$$
\begin{equation*}
\binom{x \mathbb{Q}_{k}-1}{k-2} \leq \rho \mathrm{b}\left(x \mathbb{P}_{k}+1, k\right) \leq \mathbb{Q}_{k}\binom{x \mathbb{Q}_{k}-1}{k-2} \tag{14}
\end{equation*}
$$

The exact quantity of permissible patterns enumerated by $\rho \mathrm{b}\left(x \mathbb{P}_{k}+1, k\right)$ is the upper bound given in equation (14) minus any duplicate patterns generated. The first step is to identify the $\mathbb{Q}_{k}$ unique possible location sequences. The $\mathbb{Q}_{k}$ sequences are created by performing the 'Sieve of Eratosthenes' on the integers 1 through ( $x+$ $1) \mathbb{P}_{k}$ with all the primes less than or equal to $k$. The exposed integers correspond to possible locations for prime representations in permissible patterns with a density of $k$ and a width of $(x+1) \mathbb{P}_{k}$. Each sequence of $x \mathbb{P}_{k}+1$ sieved locations that starts with a possible location contains $x \mathbb{Q}_{k}+1$ possible locations.

```

The diagram above displays sieving $(x+1) \mathbb{P}_{k}$ integers to create the $\mathbb{Q}_{k}$ possible location sequences for the permissible patterns enumerated by $\rho \mathrm{b}\left(x \mathbb{P}_{k}+1, k\right)$ when
$k=5$ and $x=1$. Here the value of $\mathbb{Q}_{k}$ is 8 , the value of $\mathbb{P}_{k}$ is 30 , and the value of $x \mathbb{P}_{k}+1$ is 31 . These possible location sequences and the permissible patterns enumerated by $\rho \mathrm{b}(31,5)$ are used as examples in the following text.

The eight possible location sequences for $\rho \mathrm{b}(31,5)$ are identified as $\mathbf{A}_{1}$ through $\mathbf{A}_{8}$ and each sequence contains nine possible locations. The upper bound of $\rho \mathrm{b}(31,5)$ is calculated as $8\binom{9-2}{5-2}$ which equals 280 .

$$
\begin{aligned}
& \mathbf{A}_{1} \text { s.....s...s.s...s.s...s.....s.s } \\
& \mathbf{A}_{2} \text { s...s.s...s.s...s.....s.s.....s } \\
& \mathbf{A}_{3} \text { s.s...s.s...s.....s.s.....s...s } \\
& \mathbf{A}_{4} \text { s...s.s...s.....s.s.....s...s.s.s } \\
& \mathbf{A}_{5} \text { s.s...s.....s.s.....s...s.s...s } \\
& \mathbf{A}_{6} \text { s...s....s.s.....s...s.s...s.s } \\
& \mathbf{A}_{7} \text { s.....s.s.....s...s.s...s.s...s } \\
& \mathbf{A}_{8} \text { s.s.....s...s.s...s.s...s.....s }
\end{aligned}
$$

The next step is to remove any permissible patterns that are duplicated in the upper bound. Duplicate permissible patterns exist when two or more possible location sequences create the same permissible pattern. The number of duplicate patterns generated by a combination of possible location sequences is determined by the quantity of common possible locations in the sequences.

$$
\begin{aligned}
& m=2 \quad \mathbf{A}_{1} \quad \text { s.....s...s.s...s.s...s.....s.s.s } \\
& \mathbf{A}_{2} \text { s...s.s...s.s...s.....s.s.....s } \\
& \mathbf{A}_{1} \cap \mathbf{A}_{2} \text { s.....s...s.s...s.....s.......s } \quad n=7 \text { common locations } \\
& m=3 \quad \mathbf{A}_{1} \quad \text { s.....s...s.s...s.s...s.....s.s.s } \\
& \mathbf{A}_{2} \text { s...s.s...s.s...s.....s.s.....s } \\
& \mathbf{A}_{4} \text { s...s.s...s.....s.s.....s...s.s.s } \\
& \mathbf{A}_{1} \bigcap \mathbf{A}_{2} \bigcap \mathbf{A}_{4} \text { s.....s...s.....s...............s } n=5 \text { common locations } \\
& \text { Examples of common possible locations }
\end{aligned}
$$

There are $\binom{\mathbb{Q}_{k}}{m}$ combinations of $m$ different possible location sequences and each combination contains $n_{m, i}$ common possible locations. The number of duplicated permissible patterns for each combination of different possible location sequences is $\binom{n_{m, i}-2}{k-2}$. When $m=1$ the quantity of common possible locations is just the number of possible locations in each sequence, or $n_{1, i}=x \mathbb{Q}_{k}+1$ for $i=1$ to $\mathbb{Q}_{k}$. This corresponds directly to the current upper bound.

$$
\rho \mathrm{b}\left(x \mathbb{P}_{k}+1, k\right) \leq \mathbb{Q}_{k}\binom{x \mathbb{Q}_{k}-1}{k-2}=\sum_{i=1}^{\binom{Q_{k}}{1}}\binom{n_{1, i}-2}{k-2}
$$

Since this is an upper bound there may be duplicate permissible patterns counted by the summation of the binomials. The number of duplicate permissible patterns is identified by determining the quantity of common possible locations for every combination of two different possible location sequences and then calculate the number of permissible patterns the common possible locations can create. There are $\binom{\mathbb{Q}_{k}}{2}$
combinations of two different possible location sequences and each combination contains $n_{2, i}$ common possible locations. Subtracting the permissible patterns created when $m=2$ from the current upper bound generates a new lower bound.

$$
\rho \mathrm{b}\left(x \mathbb{P}_{k}+1, k\right) \geq \sum_{i=1}^{\binom{Q_{k}}{1}}\binom{n_{1, i}-2}{k-2}-\sum_{i=1}^{\binom{\Theta_{k}}{2}}\binom{n_{2, i}-2}{k-2}
$$

Similar to the summation of the binomials counting the permissible patterns when $m=1$, the quantity of permissible patterns removed by the summation of the binomials when $m=2$ may also include duplicate permissible patterns. Setting $m=3$ generates the number of permissible patterns created by the common possible locations of three different possible location sequences. Adding this summation of the binomials to the current lower bound generates an improved upper bound.

$$
\rho \mathrm{b}\left(x \mathbb{P}_{k}+1, k\right) \leq \sum_{i=1}^{\binom{\mathrm{Q}_{k}}{1}}\binom{n_{1, i}-2}{k-2}-\sum_{i=1}^{\binom{\mathrm{Q}_{k}}{2}}\binom{n_{2, i}-2}{k-2}+\sum_{i=1}^{\binom{\Theta_{k}}{3}}\binom{n_{3, i}-2}{k-2}
$$

An exact value for $\rho \mathrm{b}\left(x \mathbb{P}_{k}+1, k\right)$ is generated when this procedure is repeated for every value of $m$ through $m=\mathbb{Q}_{k}$. When $m$ is even the summation of the binomials is subtracted from the current upper bound and when $m$ is odd the summation of the binomials is added to the current lower bound. It is to be noted that $\mathbb{Q}_{k}$ is even for all values of $k$ greater than 2 .

$$
\rho \mathrm{b}\left(x \mathbb{P}_{k}+1, k\right)=\sum_{i=1}^{\binom{\mathbb{Q}_{k}}{1}}\binom{n_{1, i}-2}{k-2}-\sum_{i=1}^{\binom{\mathbb{Q}_{k}}{2}}\binom{n_{2, i}-2}{k-2}+\cdots-\sum_{i=1}^{\binom{\mathbb{Q}_{k}}{Q_{k}}}\binom{n_{\mathbb{Q}_{k}, i}-2}{k-2}
$$

A double summation is made by reformatting this equation to account for the alternating sign of the summation of the binomials.

$$
\begin{equation*}
\rho \mathrm{b}\left(x \mathbb{P}_{k}+1, k\right)=\sum_{j=1}^{\mathbb{Q}_{k}} \sum_{i=1}^{\substack{\mathbb{Q}_{k} \\ j}}(-1)^{j-1}\binom{n_{j, i}-2}{k-2} \tag{15}
\end{equation*}
$$

The quantity of common possible locations, $n_{m, i}$, for each combination of $m$ different possible location sequences is a variable to be evaluated. The value of $n_{m, i}$ is investigated by manually tallying the number of common possible locations for every combination of possible location sequences of $\rho \mathrm{b}(31,5)$.

| $k=5$ <br> $m$ | $\binom{\mathbb{Q}_{5}}{m}$ | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 |
| ---: | ---: | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 1 | 8 | 8 |  |  |  |  |  |  |  |
| 2 | 28 |  | 12 |  | 4 | 12 |  |  |  |
| 3 | 56 |  |  |  | 8 | 24 | 24 |  |  |
| 4 | 70 |  |  |  |  | 6 | 50 | 14 |  |
| 5 | 56 |  |  |  |  |  | 24 | 32 |  |
| 6 | 28 |  |  |  |  |  | 4 | 24 |  |
| 7 | 8 |  |  |  |  |  |  | 8 |  |
| 8 | 1 |  |  |  |  |  |  | 1 |  |

Common possible location counts for $\rho \mathrm{b}(31,5)$

The first column is the number of possible location sequences in a combination and the second column is the number of different combinations that exist. The third row displays the 56 combinations of 3 different possible location sequences. Of these, 8 combinations have 5 common possible locations, 24 combinations have 4 common possible locations, and 24 combinations have 3 common possible locations. The number of duplicate permissible patterns identified by the values given in the third row is 8 .

$$
8 \cdot\binom{5-2}{5-2}+24 \cdot\binom{4-2}{5-2}+24 \cdot\binom{3-2}{5-2}=8+0+0=8
$$

The table of common possible location counts for permissible patterns of $\rho \mathrm{b}(31,5)$ can be modified to determine the common possible location counts for permissible patterns of $\rho \mathrm{b}(30 x+1,5)$. The cyclic nature of the possible location sequences dictate that the common possible locations are also cyclic and exist in the same quantity for every width of $\mathbb{P}_{k}$ locations in the sequence combination. The common possible location counts remain the same since there is no overlap of common possible locations.

| $k=5$ | $\binom{\mathbb{Q}_{5}}{m}$ | $8 \mathrm{x}+1$ | $7 \mathrm{x}+1$ | $6 \mathrm{x}+1$ | $5 \mathrm{x}+1$ | $4 \mathrm{x}+1$ | $3 \mathrm{x}+1$ | $2 \mathrm{x}+1$ | $\mathrm{x}+1$ |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| 1 | 8 | 8 |  |  |  |  |  |  |  |
| 2 | 28 |  |  | 12 |  | 4 | 12 |  |  |
| 3 | 56 |  |  |  |  | 8 | 24 | 24 |  |
| 4 | 70 |  |  |  |  |  | 6 | 50 | 14 |
| 5 | 56 |  |  |  |  |  |  | 24 | 32 |
| 6 | 28 |  |  |  |  |  |  | 4 | 24 |
| 7 | 8 |  |  |  |  |  |  |  | 8 |
| 8 | 1 |  |  |  |  |  | 1 |  |  |

Common possible location counts for $\rho \mathrm{b}(30 x+1,5)$

The table of common possible location counts is modified to display the number of duplicate permissible patterns by multiplying the common possible location counts and the binomial $\binom{n_{m, i}-2}{k-2}$ that describes the number of duplicated permissible patterns for a combination of possible location sequences. Also, dependant on the quantity of sequences in the combination, the sign of row is changed to account for the addition or subtraction of the duplicate patterns.

$$
\begin{aligned}
& \text { Upper Bound } 8\binom{8 x-1}{3} \\
& -\bigcap \text { of } 2 \\
& +\bigcap \text { of } 3 \\
& -\bigcap \text { of } 4 \\
& +\bigcap \text { of } 5 \\
& -\bigcap \text { of } 6 \\
& +\bigcap \text { of } 7 \\
& -\bigcap \text { of } 8 \\
& \rho \mathrm{~b}(30 x+1,5)=\overline{8\binom{8 x-1}{3}}-\overline{42\binom{6 x-1}{3}}+\overline{4\binom{4 x-1}{3}}+\overline{6\binom{3 x-1}{3}}-6\binom{2 x-1}{3} \quad \overline{\binom{x-1}{3}}
\end{aligned}
$$

The table now accounts for the duplicate permissible patterns generated by all combinations of possible location sequences. Summing each column of binomials produces a combinatorial equation for the exact value of $\rho \mathrm{b}(30 x+1,5)$. Evaluating
this combinatorial equation for $x=1$ correlates with the value provided in Table 3 for $w=31$ and $k=5$.

$$
\begin{aligned}
\rho \mathrm{b}(31,5) & =8\binom{8-1}{3}-12\binom{6-1}{3}+4\binom{4-1}{3}+6\binom{3-1}{3}-6\binom{2-1}{3}+\binom{1-1}{3} \\
& =8 \cdot 35-12 \cdot 10+4 \cdot 1+6 \cdot 0-6 \cdot 0+0 \\
& =164
\end{aligned}
$$

Performing this procedure of tallying the common possible locations in the possible location sequence combinations of $\rho \mathrm{b}\left(x \mathbb{P}_{k}+1, k\right)$ for $k=2$ through 10 generates the following combinatorial equations.

$$
\begin{aligned}
& \rho \mathrm{b}(2 x+1,2)=\binom{x-1}{0}=1 \\
& \rho \mathrm{~b}(6 x+1,3)=2\binom{2 x-1}{1}-\binom{x-1}{1} \\
& \rho \mathrm{~b}(6 x+1,4)=2\binom{2 x-1}{2}-\binom{x-1}{2} \\
& \rho \mathrm{~b}(30 x+1,5)=8\binom{8 x-1}{3}-12\binom{6 x-1}{3}+4\binom{4 x-1}{3}+6\binom{3 x-1}{3}-6\binom{2 x-1}{3}+\binom{x-1}{3} \\
& \rho \mathrm{~b}(30 x+1,6)=8\binom{8 x-1}{4}-12\binom{6 x-1}{4}+4\binom{4 x-1}{4}+6\binom{3 x-1}{4}-6\binom{2 x-1}{4}+\binom{x-1}{4} \\
& \rho \mathrm{~b}(210 x+1,7)=48\binom{48 x-1}{5}-120\binom{40 x-1}{5}-72\binom{36 x-1}{5}+160\binom{32 x-1}{5}+180\binom{30 x-1}{5} \\
& -336\binom{24 x-1}{5}-60\binom{20 x-1}{5}+216\binom{18 x-1}{5}+128\binom{16 x-1}{5}-90\binom{15 x-1}{5} \\
& -48\binom{12 x-1}{5}+90\binom{10 x-1}{5}-90\binom{9 x-1}{5}-104\binom{8 x-1}{5}+144\binom{6 x-1}{5} \\
& -15\binom{5 x-1}{5}-20\binom{4 x-1}{5}-21\binom{3 x-1}{5}+12\binom{2 x-1}{5}-\binom{x-1}{5} \\
& \rho \mathrm{~b}(210 x+1,8)=48\binom{48 x-1}{6}-120\binom{40 x-1}{6}-72\binom{36 x-1}{6}+160\binom{32 x-1}{6}+180\binom{30 x-1}{6} \\
& -336\binom{24 x-1}{6}-60\binom{20 x-1}{6}+216\binom{18 x-1}{6}+128\binom{16 x-1}{6}-90\binom{15 x-1}{6} \\
& -48\binom{12 x-1}{6}+90\binom{10 x-1}{6}-90\binom{9 x-1}{6}-104\binom{8 x-1}{6}+144\binom{6 x-1}{6} \\
& -15\binom{5 x-1}{6}-20\binom{4 x-1}{6}-21\binom{3 x-1}{6}+12\binom{2 x-1}{6}-\binom{x-1}{6} \\
& \rho \mathrm{~b}(210 x+1,9)=48\binom{48 x-1}{7}-120\binom{40 x-1}{7}-72\binom{36 x-1}{7}+160\binom{32 x-1}{7}+180\binom{30 x-1}{7} \\
& -336\binom{24 x-1}{7}-60\binom{20 x-1}{7}+216\binom{18 x-1}{7}+128\binom{16 x-1}{7}-90\binom{15 x-1}{7} \\
& -48\binom{12 x-1}{7}+90\binom{10 x-1}{7}-90\binom{9 x-1}{7}-104\binom{8 x-1}{7}+144\binom{6 x-1}{7} \\
& -15\binom{5 x-1}{7}-20\binom{4 x-1}{7}-21\binom{3 x-1}{7}+12\binom{2 x-1}{7}-\binom{x-1}{7} \\
& \rho \mathrm{~b}(210 x+1,10)=48\binom{48 x-1}{8}-120\binom{40 x-1}{8}-72\binom{36 x-1}{8}+160\binom{32 x-1}{8}+180\binom{30 x-1}{8} \\
& -336\binom{24 x-1}{8}-60\binom{20 x-1}{8}+216\binom{18 x-1}{8}+128\binom{16 x-1}{8}-90\binom{15 x-1}{8} \\
& -48\binom{12 x-1}{8}+90\binom{10 x-1}{8}-90\binom{9 x-1}{8}-104\binom{8 x-1}{8}+144\binom{6 x-1}{8} \\
& -15\binom{5 x-1}{8}-20\binom{4 x-1}{8}-21\binom{3 x-1}{8}+12\binom{2 x-1}{8}-\binom{x-1}{8}
\end{aligned}
$$

The binomials in these combinatorial equations are all based on sets of elements that are linear functions of $x$, therefore the combinatorial equations can be converted into polynomial equations of $x$. The order of the polynomial is based on the subgroup size which is $k-2$ for each binomial. The following are polynomial equations equivalent to the combinatorial equations of $\rho \mathrm{b}\left(x \mathbb{P}_{k}+1, k\right)$ for $k=2$ through 10.

$$
\begin{aligned}
& \rho \mathrm{b}(2 x+1,2)= 1 \\
& \rho \mathrm{~b}(6 x+1,3)= \frac{3}{1} x-\frac{1}{1} \\
& \rho \mathrm{~b}(6 x+1,4)= \frac{7}{2} x^{2}-\frac{9}{2} x+\frac{2}{2} \\
& \rho \mathrm{~b}(30 x+1,5)= \frac{1875}{6} x^{3}-\frac{1050}{6} x^{2}+\frac{165}{6} x-\frac{6}{6} \\
& \rho \mathrm{~b}(30 x+1,6)= \frac{18631}{24} x^{4}-\frac{18750}{24} x^{3}+\frac{6125}{24} x^{2}-\frac{750}{24} x+\frac{24}{24} \\
& \rho \mathrm{~b}(210 x+1,7)= \frac{2927695365}{120} x^{5}-\frac{670995465}{120} x^{4}+\frac{54665625}{120} x^{3}-\frac{1929375}{120} x^{2} \\
&+\frac{28770}{120} x-\frac{120}{120} \\
& \rho \mathrm{~b}(210 x+1,8)= \frac{182135041495}{720} x^{6}-\frac{61481602665}{720} x^{5}+\frac{7828280425}{720} x^{4}-\frac{472696875}{720} x^{3} \\
& \quad \frac{139800}{720} x^{2}-\frac{185220}{720} x+\frac{720}{720} \\
& \rho \mathrm{~b}(210 x+1,9)= \frac{10842356545125}{5040} x^{7}-\frac{5099781161860}{5040} x^{6}+\frac{942717907530}{5040} x^{5}-\frac{87676740760}{5040} x^{4} \\
& \quad \frac{43533125}{5040} x^{3}-\frac{112606900}{5040} x^{2}+\frac{1372140}{5040} x-\frac{5040}{5040} \\
& \rho \mathrm{~b}(210 x+1,10)= \frac{621234485684071}{40320} x^{8}-\frac{390324835624500}{40320} x^{7}+\frac{99445732656270}{40320} x^{6} \\
& 40320 \\
& \hline
\end{aligned}
$$

Even though some of these polynomial equations can be simplified, such as the polynomial equation for $\rho \mathrm{b}(6 x+1,4)$, the polynomials are left in raw form so the coefficients and their structure can be investigated.

$$
\rho \mathrm{b}(6 x+1,4)=\frac{7}{2} x^{2}-\frac{9}{2} x+\frac{2}{2}=\frac{1}{2}(7 x-2)(x-1)
$$

The combinatorial equations are converted to polynomial equations by expanding the binomials and canceling common terms.

$$
\text { e.g. } \quad\binom{8 x-1}{3}=\frac{(8 x-1)!}{(8 x-4)!3!}=\frac{(8 x-1)(8 x-2)(8 x-3)}{3!}
$$

The numerator in each expansion is converted into a falling factorial. The falling factorial is denoted as $(x)^{n}$.

$$
(x)^{\underline{n}}=x(x-1)(x-2) \cdots(x-n+1)
$$

The permissible pattern functions are now converted to a sum of falling factorial multiples divided by a factorial.

$$
\begin{aligned}
\rho \mathrm{b}(30 x+1,5)=\frac{1}{3!} & \left(8(8 x-1)^{\underline{3}}-12(6 x-1)^{\underline{3}}+4(4 x-1)^{\underline{3}}\right. \\
& \left.+6(3 x-1)^{\underline{3}}-6(2 x-1)^{\underline{3}}+(x-1)^{\underline{3}}\right)
\end{aligned}
$$

The presence of the falling factorials invoke using an identity for signed Stirling numbers of the first kind. The signed Stirling numbers of the first kind are represented as $s(n, i)$.

$$
(x)^{n}=\sum_{i=0}^{n} s(n, i) x^{i}
$$

Substituting the Stirling number identity for each falling factorial and then regrouping the terms converts the permissible pattern counting function into a summation.

$$
\begin{array}{r}
\rho \mathrm{b}(30 x+1,5)=\frac{1}{3!} \sum_{i=0}^{3} s(3, i)\left(8(8 x-1)^{i}-12(6 x-1)^{i}+4(4 x-1)^{i}\right. \\
\left.+6(3 x-1)^{i}-6(2 x-1)^{i}+(x-1)^{i}\right)
\end{array}
$$

The signed Stirling numbers of the first kind are replaced with unsigned Stirling numbers of the first kind with the appropriate sign, the powers are expanded, and then the terms are again regrouped. Unsigned Stirling numbers of the first kind represent the number of ways to permute a set of $n$ elements into $i$ cycles. The unsigned Stirling numbers of the first kind are denoted as $\left[\begin{array}{c}n \\ i\end{array}\right]$ where $\left[\begin{array}{c}n \\ i\end{array}\right]=|s(n, i)|$.

$$
\begin{array}{r}
\rho \mathrm{b}(30 x+1,5)=\frac{1}{3!}\left(1875 x^{3} \sum_{i=3}^{3}\left[\begin{array}{l}
3 \\
i
\end{array}\right]\binom{i}{3}-175 x^{3} \sum_{i=2}^{3}\left[\begin{array}{l}
3 \\
i
\end{array}\right]\binom{i}{2}\right. \\
\left.+15 x^{3} \sum_{i=1}^{3}\left[\begin{array}{l}
3 \\
i
\end{array}\right]\binom{i}{1}-\sum_{i=0}^{3}\left[\begin{array}{l}
3 \\
i
\end{array}\right]\binom{i}{0}\right)
\end{array}
$$

The summation of unsigned Stirling numbers of the first kind paired with a binomial allows another identity to be used.

$$
\sum_{i=a}^{n}\left[\begin{array}{l}
n \\
i
\end{array}\right]\binom{i}{a}=\left[\begin{array}{c}
n+1 \\
i+1
\end{array}\right]
$$

The identity is applied to the summations.

$$
\rho \mathrm{b}(30 x+1,5)=\frac{1}{3!}\left(1875\left[\begin{array}{l}
4 \\
4
\end{array}\right] x^{3}-175\left[\begin{array}{l}
4 \\
3
\end{array}\right] x^{2}+15\left[\begin{array}{l}
4 \\
2
\end{array}\right] x-\left[\begin{array}{l}
4 \\
1
\end{array}\right]\right)
$$

Finally, the unsigned Stirling numbers of the first kind are replaced with the signed Stirling numbers of the first kind to create a polynomial in terms of $x$.

$$
\rho \mathrm{b}(30 x+1,5)=\frac{1}{3!}\left(1875 s(4,4) x^{3}+175 s(4,3) x^{2}+15 s(4,2) x+s(4,1)\right)
$$

A brief table of signed Stirling numbers of the first kind is shown below for reference.

| $m$ | value of $n$ |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0 |  |  |  |  |  |  |  |  |  | 1 |
| 1 |  |  |  |  |  |  |  |  | 1 | 0 |
| 2 |  |  |  |  |  |  |  | 1 | -1 | 0 |
| 3 |  |  |  |  |  |  | 1 | -3 | 2 | 0 |
| 4 |  |  |  |  |  | 1 | -6 | 11 | -6 | 0 |
| 5 |  |  |  |  | 1 | -10 | 35 | -50 | 24 | 0 |
| 6 |  |  |  | 1 | -15 | 85 | -225 | 274 | -120 | 0 |
| 7 |  |  | 1 | -21 | 175 | -735 | 1624 | -1764 | 720 | 0 |
| 8 |  | 1 | -28 | 322 | -1960 | 6769 | -13132 | 13068 | -5040 | 0 |
| 9 | 1 | -36 | 546 | -4536 | 22449 | -67284 | 118124 | -109584 | 40320 | 0 |

The polynomial equation representing $\rho \mathrm{b}\left(x \mathbb{P}_{k}+1, k\right)$ consists of $k-1$ terms and the coefficients of the terms are multiples of $s(k-1, i)$ for $i=1$ to $k-1$. The polynomial equations of $\rho \mathrm{b}\left(x \mathbb{P}_{k}+1, k\right)$ for $k=2$ through 10 are rewritten with the factors that are Stirling numbers of the first kind underlined. Also, the common factorial has been extracted.

$$
\begin{aligned}
& \rho \mathrm{b}(2 x+1,2)=\frac{1}{0!}(\underline{1})=1 \\
& \rho \mathrm{~b}(6 x+1,3)=\frac{1}{1!}(3 \cdot \underline{1} x-\underline{1}) \\

& \left.-343 \cdot 125 \cdot 15 \cdot \underline{67284} x^{3}+49 \cdot 25 \cdot 7 \cdot \underline{118124} x^{2}-7 \cdot 5 \cdot 3 \cdot \underline{109584} x+\underline{40320}\right)
\end{aligned}
$$

The structure of the factors that remain can be described using the analogy of counting the numbers that do not contain all digits 1 through $a-1$ simultaneously when the numbers 0 through $a^{n}-1$ are written in base $a$. The arrays below display the analogy for $a=3$ with $n=0,1,2$, and 3 . The 'lined-out' numbers are not counted because the digits 1 and 2 are both present. The count is expressed as the two variable function $f(n, a)$.

| $f(0,3)=1$ | $f(1,3)=3$ |  |  | $f(2,3)=7$ |  |  | $f(3,3)=15$ |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 0 |  | 2 |  |  |  | 000 | 100 | 200 |
|  |  |  |  |  |  |  | 001 | 101 | 20017 |
|  |  |  |  |  |  |  | 002 | 4014 | 202 |
|  |  |  |  | 00 | 10 | 20 | 010 | 110 | 2uty |
|  |  | 1 |  | 01 | 11 | 21 | 011 | 111 | 2AF |
|  |  |  |  | 02 | 12 | 22 | 012 | 112 | 212 |
|  |  |  |  |  |  |  | 020 | 1440 | 220 |
|  |  |  |  |  |  |  | 021 | 121 | 221 |
|  |  |  |  |  |  |  | 022 | 142\% | 222 |

The variable $a$ represents the base to be used for counting. When counting in base $a$ there are $a$ digits available, namely the digits $0,1,2, \ldots, a-1$. Valid bases for counting must have at least 2 different digits, meaning the variable $a$ must be greater than or equal to 2 . The variable $n$ represents the duration of the counting where the numbers to be counted start a 0 and continue through $a^{n}-1$.

The value of $a^{n}-1=0$ for all $a$ when $n=0$ and the largest number to be counted is 0 . The single digit 0 is the only number counted, therefore when $n=0$ the quantity of numbers counted equals 1 .

$$
\begin{equation*}
f(0, a)=1 \quad \text { for all } \quad a \geq 2 \tag{16}
\end{equation*}
$$

The definition of the function is counting the numbers that do not contain all digits 1 through $a-1$. The digits 0 and 1 are used for counting in base 2. Every number written in base 2 , except 0 , contains at least one 1 . The only number counted is 0 , therefore when $a=2$ the quantity of numbers counted equals 1 .

$$
f(n, 2)=1 \quad \text { for all } \quad n \geq 0
$$

Numbers written in base $a$ that are less than $a^{n}$ have a maximum of $n$ digits. When $n=a-2$ there is a maximum of $a-2$ digits contained in the numbers being counted but there are $a-1$ different digits from $1,2, \ldots, a-1$. Numbers less than $a^{a-2}$ cannot simultaneously contain all $a-1$ digits, therefore when $n \leq a-2$ the quantity of numbers counted is $a^{n}$.

$$
f(n, a)=a^{n} \quad \text { for all } \quad n \leq a-2
$$

When $n=a-1$ there is a maximum of $a-1$ digits contained in the numbers being counted and there is also $a-1$ different digits from $1,2, \ldots, a-1$. Numbers containing $a-1$ digits can simultaneously contain one each of these $a-1$ different digits. There are $(a-1)$ ! permutations of the $a-1$ different digits and each
permutation represents a number that is not counted, therefore when $n=a-1$ the quantity of numbers counted is $a^{a-1}$ less the $(a-1)$ ! permutations of the $a-1$ different digits.

$$
f(a-1, a)=a^{a-1}-(a-1)!
$$

The quantity of numbers for $f(n, a)$ can be determined by arranging the numbers 0 through $a^{n}-1$ into columns of $a^{n-1}-1$ consecutive numbers. The quantity of numbers in the first column that match the criteria for the analogy is $f(n-1, a)$ since the first digit is a zero. Also, in each of the remaining $a-1$ columns the quantity of numbers that match the criteria is $f(n-1, a)$ less a quantity $b_{n, a}$ since the first digit is not a zero.

$$
\begin{aligned}
f(n, a) & =f(n-1, a)+(a-1)\left(f(n-1, a)-b_{n, a}\right) \\
& =a f(n-1, a)-(a-1) b_{n, a}
\end{aligned}
$$

Cascading this equation permits $f(n, a)$ to be expressed in terms of previously calculated values of $f(n-i, a)$.

$$
\begin{aligned}
f(m+1, a) & =a f(m, a)-(a-1) b_{m+1, a} \\
f(m+2, a) & =a^{2} f(m, a)-(a-1)\left(a b_{m+1, a}+b_{m+2, a}\right) \\
f(m+3, a) & =a^{3} f(m, a)-(a-1)\left(a^{2} b_{m+1, a}+a b_{m+2, a}+b_{m+3, a}\right) \\
\vdots & \\
f(m+n, a) & =a^{n} f(m, a)-(a-1) \sum_{i=1}^{n} a^{n-i} b_{m+i, a}
\end{aligned}
$$

Setting $m=0$ allows $f(m, a)$ to be canceled due to equation (16), thereby producing a summation of the $b_{i+1, a}$ quantities matched with powers of $a$.

$$
f(n, a)=a^{n}-(a-1) \sum_{i=0}^{n-1} a^{n-i-1} b_{i+1, a}
$$

Returning to the analogy, the value of $b_{n, a}$ is the quantity of numbers that are not counted due to the additional non-zero digit in the first column. The value $b_{n, a}$ counts the ( $a-2$ )! permutations of $a-1$ nonempty subsets of the $n$ digits. Stirling numbers of the second kind represented as $\left\{\begin{array}{c}n \\ a-1\end{array}\right\}$ count the number of ways to partition a set of $n$ elements into $a-1$ nonempty subsets. Using this notation for Stirling numbers of the second kind the value of $b_{n, a}$ is expressed by the following equation.

$$
b_{n, a}=(a-2)!\left\{\begin{array}{c}
n \\
a-1
\end{array}\right\}
$$

Substituting the equivalent product for each $b_{i, a}$ produces a summation of Stirling numbers of the second kind matched with powers of $a$.

$$
f(n, a)=a^{n}-(a-1)!\sum_{i=1}^{n} a^{n-i}\left\{\begin{array}{c}
i \\
a-1
\end{array}\right\}
$$

Using an identity of Stirling numbers of the second kind, a summation of powers multiplied by Stirling numbers of the second kind creates a single Stirling number of the second kind.

$$
\left\{\begin{array}{c}
n+1 \\
a
\end{array}\right\}=\sum_{i=0}^{n} a^{n-i}\left\{\begin{array}{c}
i \\
a-1
\end{array}\right\}
$$

Applying this identity to the equation produces a factorial times a single Stirling number of the second kind.

$$
f(n, a)=a^{n}-(a-1)!\left\{\begin{array}{c}
n+1 \\
a
\end{array}\right\}
$$

The Stirling number of the second kind recurrence identity is used to create a sum of two Stirling numbers of the second kind.

$$
\left\{\begin{array}{c}
n+1 \\
a
\end{array}\right\}=a\left\{\begin{array}{l}
n \\
a
\end{array}\right\}+\left\{\begin{array}{c}
n \\
a-1
\end{array}\right\}
$$

When this identity is applied to the equation two Stirling numbers of the second kind are produced. Each Stirling number of the second kind is now matched with a factorial of the subset size.

$$
f(n, a)=a^{n}-a!\left\{\begin{array}{l}
n \\
a
\end{array}\right\}-(a-1)!\left\{\begin{array}{c}
n \\
a-1
\end{array}\right\}
$$

A Stirling number of the second kind multiplied by a factorial of the subset size invokes the usage of another identity.

$$
a!\left\{\begin{array}{l}
n \\
a
\end{array}\right\}=\sum_{i=0}^{a}-1^{a-i}\binom{a}{i} i^{n}
$$

Two summations of an alternating sign binomial times a power of the summation index are produced by applying this identity to the equations products of factorials and Stirling numbers of the second kind.

$$
f(n, a)=a^{n}-\sum_{i=0}^{a}-1^{a-i}\binom{a}{i} i^{n}-\sum_{i=0}^{a-1}-1^{a-1-i}\binom{a-1}{i} i^{n}
$$

The $a$ th term is extracted from the first summation and canceled when subtracted from the existing $a^{n}$ value. The remaining $a-1$ terms are paired with the $a-1$ terms of the second summation leaving a single summation of alternating sign differences of binomials times a power of the summation index.

$$
f(n, a)=\sum_{i=0}^{a-1}-1^{a-1-i}\left(\binom{a}{i}-\binom{a-1}{i}\right) i^{n}
$$

The binomial recurrence identity is used to create a single binomial.

$$
\binom{a-1}{i-1}=\binom{a}{i}-\binom{a-1}{i}
$$

A simple summation of alternating sign binomials times a power of the summation index is produced by applying this identity to the equation.

$$
f(n, a)=\sum_{i=1}^{a-1}-1^{a-1-i}\binom{a-1}{i-1} i^{n}
$$

One last simplification is made by expanding the summation and then summing in reverse order.

$$
f(n, a)=\sum_{i=1}^{a-1}-1^{i-1}\binom{a-1}{i}(a-i)^{n}
$$

The function $f(n, a)$ described above is used to determine factors of coefficients in the polynomial equations for $\rho \mathrm{b}\left(x \mathbb{P}_{k}+1, k\right)$. The function $f(n, a)$ is formally denoted $\mathrm{E}_{a}^{n}$. Calculated values of the function $\mathrm{E}_{a}^{n}$ are given in Table 4.

$$
\begin{equation*}
\mathrm{E}_{a}^{n}=\sum_{i=1}^{a-1}-1^{i-1}\binom{a-1}{i}(a-i)^{n} \tag{17}
\end{equation*}
$$

The analogy given for the function $\mathrm{E}_{a}^{n}$ is related to admissible prime tuples when the digits in the analogy represent the residue classes of specific primes. The digit 0 in the analogy represents an unused residue class for a prime of magnitude $a$, while the remaining digits represent filled residue classes. When the digits 1 through $a-1$ are all represented causing the number to not be counted, the corresponding tuple is not admissible due to all residue classes being used. The coefficients of the $\rho \mathrm{b}\left(x \mathbb{P}_{k}+1, k\right)$ polynomial equations have factors related to each prime less than or equal to $k$. Each factor is the value of $\mathrm{E}_{a}^{n}$ with $a$ being the prime involved and $n$ representing the exponent of the coefficients term.

All the components required to create a closed form equation for $\rho \mathrm{b}\left(x \mathbb{P}_{k}+1, k\right)$ are available leaving only the construction of the equation. First, the equation is a sum of $k-1$ terms, each being a coefficient times a power of $x$ divided by $(k-2)$ !. Also, each coefficient is a multiple of a signed Stirling number of the first kind based on $k$ and the term exponent $i$.

$$
\rho \mathrm{b}\left(x \mathbb{P}_{k}+1, k\right)=\frac{1}{(k-2)!} \sum_{i=0}^{k-2} C_{i} s(k-1, i+1) x^{i}
$$

Finally, the remaining portion of the coefficient is a product of the $\mathrm{E}_{a}^{n}$ values for each prime less than or equal to $k$. The value of $n$ is the term exponent $i$ and the value of $a$ is the prime $p_{j}$. Here $\pi(k)$ is the prime counting function representing the number of primes less than or equal to $k$.

$$
C_{i}=\prod_{j=1}^{\pi(k)} \mathrm{E}_{p_{j}}^{i}
$$

The signed Stirling numbers account for the alternating signs of the terms. The closed form equation for $\rho \mathrm{b}\left(x \mathbb{P}_{k}+1, k\right)$ is now complete and provides the count of permissible patterns with a density of $k$ when the width is a multiple of the primorial of $k$ plus one.

$$
\begin{equation*}
\rho \mathrm{b}\left(x \mathbb{P}_{k}+1, k\right)=\frac{1}{(k-2)!} \sum_{i=0}^{k-2}\left(s(k-1, i+1) x^{i} \prod_{j=1}^{\pi(k)} \mathrm{E}_{p_{j}}^{i}\right) \tag{18}
\end{equation*}
$$

$\pi()$ is the prime counting function
and $p_{j}$ is the $j$ th prime number
$\rho \mathrm{b}\left(x \mathbb{P}_{k}, k\right)=0$
Develop closed form for $\rho \mathrm{f}\left(x \mathbb{P}_{k}+1, k\right)$

$$
\begin{aligned}
\rho \mathrm{f}(2 x+1,2) & =\binom{x}{1} \\
\rho \mathrm{f}(6 x+1,3) & =2\binom{2 x}{2}-\binom{x}{2} \\
\rho \mathrm{f}(30 x+1,5) & =8\binom{8 x}{4}-12\binom{6 x}{4}+4\binom{4 x}{4}+6\binom{3 x}{4}-6\binom{2 x}{4}+\binom{x}{4} \\
\rho \mathrm{~b}(2 x+1,2) & =\frac{1}{1!}(\underline{1} x) \\
\rho \mathrm{b}(6 x+1,3) & =\frac{1}{2!}\left(7 \cdot \underline{1} x^{2}-3 \cdot \underline{1} x\right) \\
\rho \mathrm{b}(30 x+1,5) & =\frac{1}{4!}\left(601 \cdot 31 \cdot \underline{1} x^{4}-125 \cdot 15 \cdot \underline{6} x^{3}+25 \cdot 7 \cdot \underline{11} x^{2}-5 \cdot 3 \cdot \underline{6} x\right)
\end{aligned}
$$

$$
\begin{equation*}
\rho \mathrm{f}\left(x \mathbb{P}_{k}+1, k\right)=\frac{1}{(k-1)!} \sum_{i=1}^{k-1}\left(s(k-1, i) x^{i} \prod_{j=1}^{\pi(k)} \mathrm{E}_{p_{j}}^{i}\right) \tag{19}
\end{equation*}
$$

$\rho \mathrm{f}\left(x \mathbb{P}_{k}, k\right)=\rho \mathrm{f}\left(x \mathbb{P}_{k}+1, k\right)-\rho \mathrm{b}\left(x \mathbb{P}_{k}+1, k\right)$
$\rho \mathrm{f}\left(x \mathbb{P}_{k}-1, k\right)=\rho \mathrm{f}\left(x \mathbb{P}_{k}, k\right)$
Develop closed form for $\rho\left(x \mathbb{P}_{k}+1, k\right)$
$\rho\left(x \mathbb{P}_{k}, k\right)=\rho\left(x \mathbb{P}_{k}+1, k\right)-\rho \mathrm{f}\left(x \mathbb{P}_{k}+1, k\right)$
$\rho\left(x \mathbb{P}_{k}-1, k\right)=\rho\left(x \mathbb{P}_{k}, k\right)-\rho \mathrm{f}\left(x \mathbb{P}_{k}, k\right)$
$\rho\left(x \mathbb{P}_{k}-2, k\right)=\rho\left(x \mathbb{P}_{k}-1, k\right)-\rho \mathbf{f}\left(x \mathbb{P}_{k}-1, k\right)$

Width of pattern for first occurrence of any density ...
Reference Table 5 (verified using exhaustive search methods)
Identify 3159 as first counter-example to Hardy-Littlewood 2nd conjecture

Identify 5943 as last occurrence
5943 needs final verification

Violation of 'large sieve' ...
Results applied to Hardy-Littlewood 'k-tuples' conjecture
Consequences of results

I would like to acknowledge a few people and organizations that have made this work possible. First, to my wife, Tracy, as she has endured and nurtured my eccentricities while I pursued this problem as a hobby, or as she calls it 'my obsession'. Next, Prof. Jörg Waldvogel from the Seminar for Applied Mathematics at ETHZ for the guidance, challenges, and thought provoking emails. Finally, I am grateful for the resources and funding provided by Operational Techniques, Inc.

misc text and equations not yet used

Binomial coefficients created from possible location counts for $\rho \mathrm{b}\left(x \mathbb{P}_{5}+b, 5\right)$

Polynomial equations for $\rho \mathrm{b}\left(x \mathbb{P}_{5}+b, 5\right)$

$$
\begin{aligned}
\rho \mathrm{b}(30 x+1,5) & =\frac{1}{3!}\left(1875 x^{3}-1050 x^{2}+165 x-6\right) \\
\rho \mathrm{b}(30 x+3,5) & =\frac{1}{3!}\left(952 x^{3}-300 x^{2}+20 x+0\right) \\
\rho \mathrm{b}(30 x+5,5) & =\frac{1}{3!}\left(952 x^{3}-300 x^{2}+20 x+0\right) \\
\rho \mathrm{b}(30 x+7,5) & =\frac{1}{3!}\left(1785 x^{3}+27 x^{2}-30 x+0\right) \\
\rho \mathrm{b}(30 x+9,5) & =\frac{1}{3!}\left(952 x^{3}+252 x^{2}+8 x+0\right) \\

\end{aligned}
$$

Additional information about $\rho \mathrm{b}()$ must be acquired to determine values of $\rho \mathrm{b}\left(x \mathbb{P}_{k}+b, k\right)$ as this closed form equation is only for $b=1$. The counting function $\rho \mathrm{b}()$ is erratic as evidenced by the values in Table 3 inducing the requirement of investigating each value of $b$ independently. Equation (7) can be reworked to express $\rho \mathrm{b}()$ with values of $\rho \mathrm{f}()$ by extracting the term for $i=w$ from the summation and reordering the result.

$$
\begin{aligned}
\rho \mathrm{f}(w, k) & =\sum_{i=k}^{w} \rho \mathrm{~b}(i, k) \\
& =\rho \mathrm{b}(w, k)+\sum_{i=k}^{w-1} \rho \mathrm{~b}(i, k) \\
& =\rho \mathrm{b}(w, k)+\rho \mathrm{f}(w-1, k) \\
\rho \mathrm{b}(w, k) & =\rho \mathrm{f}(w, k)-\rho \mathrm{f}(w-1, k)
\end{aligned}
$$

The table of common possible locations for $\rho \mathrm{b}\left(x \mathbb{P}_{k}+1, k\right)$ was created from possible location sequences with the restriction that the boundary locations are prime representations. For widths of $x \mathbb{P}_{k}+1$ sieved locations a possible location sequence that starts on with a prime representation in the leading boundary location also has a prime representation in the trailing boundary location. This is only true for widths $x \mathbb{P}_{k}+b$ where $b=1$. Relieving the restriction so only the leading boundary location is a prime representation creates possible location sequences for the counting function $\rho \mathrm{f}()$. A possible location sequence for $\rho \mathrm{f}\left(x \mathbb{P}_{k}+b, k\right)$ is generated for every prime representation in the sieved locations. The sieved locations are cyclic with a period of $\mathbb{P}_{k}$ so only the prime representations in the first $\mathbb{P}_{k}$ sieved locations produce unique possible location sequences. A quantity of $\mathbb{Q}_{k}$ prime representations exist in the first $\mathbb{P}_{k}$ sieved locations producing $\mathbb{Q}_{k}$ possible location sequences.

The $\mathbb{Q}_{k}$ possible location sequences for $\rho \mathrm{f}\left(x \mathbb{P}_{k}+1, k\right)$ are the same as those created for $\rho \mathrm{b}\left(x \mathbb{P}_{k}+1, k\right)$. Removing the trailing boundary location from each possible location sequence of $\rho \mathrm{f}\left(x \mathbb{P}_{k}+1, k\right)$ creates the possible location sequences for $\rho \mathrm{f}\left(x \mathbb{P}_{k}, k\right)$. The coefficients of the binomials in the combinatorial equations for $\rho \mathrm{f}\left(x \mathbb{P}_{k}, k\right)$ remain the same as those for $\rho \mathrm{b}\left(x \mathbb{P}_{k}+1, k\right)$ but the terms in the binomials must account for removing the trailing boundary location and relieving
the restriction that the trailing boundary location is a prime representation. The binomial set sizes remain the same and the binomial subset sizes are one element larger than the corresponding sizes in the binomials used for $\rho \mathrm{b}\left(x \mathbb{P}_{k}+1, k\right)$. The generated combinatorial equations are converted to polynomials and the coefficients are factored. Finally, the polynomial equations are transformed into a closed form equation.

Combinatorial equations for $\rho \mathrm{f}\left(x \mathbb{P}_{k}, k\right)$.

$$
\begin{aligned}

\rho \mathrm{f}(2 x, 2)= & \frac{1}{1!}(\underline{1} x-\underline{1}) \\
\rho \mathrm{f}(6 x, 3)= & \frac{1}{2!}\left(7 \cdot \underline{1} x^{2}-3 \cdot \underline{3} x+\underline{2}\right) \\
\rho \mathrm{f}(30 x, 5)= & \frac{1}{4!}\left(601 \cdot 31 \cdot \underline{1} x^{4}-125 \cdot 15 \cdot \underline{10} x^{3}+25 \cdot 7 \cdot \underline{35} x^{2}-5 \cdot 3 \cdot \underline{50} x+\underline{24}\right) \\
\rho \mathrm{f}(210 x, 7)= & \frac{1}{6!}\left(116929 \cdot 12265 \cdot 127 \cdot \underline{1} x^{6}-16807 \cdot 2765 \cdot 63 \cdot \underline{21} x^{5}+2401 \cdot 601 \cdot 31 \cdot \underline{175} x^{4}\right. \\
\quad & \left.\quad-343 \cdot 125 \cdot 15 \cdot \underline{735} x^{3}+49 \cdot 25 \cdot 7 \cdot \underline{1624} x^{2}-7 \cdot 5 \cdot 3 \cdot \underline{1764} x+\underline{720}\right)
\end{aligned}
$$

Closed form equation for $\rho \mathrm{f}\left(x \mathbb{P}_{k}, k\right)$.

$$
\begin{equation*}
\rho \mathrm{f}\left(x \mathbb{P}_{k}, k\right)=\frac{1}{(k-1)!} \sum_{i=1}^{k-1}\left(s(k, i+1) x^{i} \prod_{j=1}^{\pi(k)} \mathrm{E}_{p_{j}}^{i}\right) \tag{20}
\end{equation*}
$$

Again, additional information about $\rho f()$ must be acquired to determine values of $\rho \mathrm{f}\left(x \mathbb{P}_{k}+b, k\right)$ as the closed form equation is only for $b=1$. The counting function $\rho \mathrm{f}()$ is weakly increasing as evidenced by the equality $\rho \mathrm{f}(2 x+2, k)=\rho \mathrm{f}(2 x+1, k)$.

Equation (6) can be reworked to express $\rho \mathrm{f}()$ with values of $\rho()$ by extracting the term for $i=w$ from the summation and reordering the result.

$$
\begin{aligned}
\rho(w, k) & =\sum_{i=k}^{w} \rho \mathrm{f}(i, k) \\
& =\rho \mathrm{f}(w, k)+\sum_{i=k}^{w-1} \rho \mathrm{f}(i, k) \\
& =\rho \mathrm{f}(w, k)+\rho(w-1, k) \\
\rho \mathrm{f}(w, k) & =\rho(w, k)-\rho(w-1, k)
\end{aligned}
$$

Using the method that created the equations for $\rho \mathrm{f}\left(x \mathbb{P}_{k}, k\right)$ the equations for $\rho\left(x \mathbb{P}_{k}-1, k\right)$ can be created by relieving the restriction that the leading boundary location is a prime representation. Possible location sequences for $\rho\left(x \mathbb{P}_{k}-1, k\right)$ are generated at every sieved location. The sieved locations are cyclic with a period of $\mathbb{P}_{k}$ this time producing a total of $\mathbb{P}_{k}$ possible location sequences. Of these $\mathbb{P}_{k}$ possible location sequences there are $\mathbb{Q}_{k}$ sequences that have a prime representation in the leading boundary.

The $\mathbb{Q}_{k}$ possible location sequences that have a prime representation in the leading boundary are the same as those created for $\rho f\left(x \mathbb{P}_{k}, k\right)$. The difference again occurs in the combinatorial equations. The coefficients of the binomials in the combinatorial equations for $\rho\left(x \mathbb{P}_{k}-1, k\right)$ remain the same as those for $\rho \mathrm{f}\left(x \mathbb{P}_{k}, k\right)$ but the terms in the binomials must account removing the leading boundary location and relieving the restriction that the leading boundary is a prime representation. The binomial set sizes remain the same and the binomial subset sizes are one element larger than the corresponding sizes in the binomials used for $\rho \mathrm{f}\left(x \mathbb{P}_{k}, k\right)$.

The combinatorial equations that represent the remaining $\mathbb{P}_{k}-\mathbb{Q}_{k}$ possible location sequences have binomial set sizes that are one element smaller while the binomial subset sizes remain the same. The generated combinatorial equations are converted to polynomials and the coefficients are factored. Finally, the polynomial equations are transformed into a closed form equation.

Combinatorial equations for $\rho\left(x \mathbb{P}_{k}-1, k\right)$.

$$
\begin{aligned}
\rho(2 x-1,2)= & \binom{x}{2}+\binom{x-1}{2} \\
\rho(6 x-1,3)= & 4\binom{2 x}{3}+2\binom{2 x-1}{3}-5\binom{x}{3}-\binom{x-1}{3} \\
\rho(30 x-1,5)= & 22\binom{8 x}{5}+8\binom{8 x-1}{5}-48\binom{6 x}{5}-12\binom{6 x-1}{5} \\
& +26\binom{4 x}{5}+4\binom{4 x-1}{5}+54\binom{3 x}{5}+6\binom{3 x-1}{5} \\
& \quad-24\binom{2 x}{5}-6\binom{2 x-1}{5}+29\binom{x}{5}+\binom{x-1}{5}
\end{aligned}
$$
